PY 221 Statistics & Research Methods I

Dr. Valenti

# Outline for Ch. 12 Correlation – using JAMOVl

---

- 1. How to run correlation using JAMOVl**
2. How to interpret JAMOVl output
3. How to write up results using APA style

# Correlation using JAMOVl: Example Study

---

- What relationships exist between students' exam performance, exam anxiety, and the time students spend studying?
- Participants:
  - 103 students
- Measures (variable names from data file are in *italics*)
  - Time spent "revising" aka studying (in **hours**) - *Revise*
  - Exam performance (**% grade**) - *Exam*
  - Exam Anxiety (the EAQ, **score out of 100**) - *Anxiety*
  - Gender - **Gender**

# Correlation: What hypotheses are we testing? (review)

---

## null hypothesis?

When  $r$  is closer to 0,  $p$  will be larger.

- $H_0 : \rho = 0$
- There is **no relationship** between exam anxiety and exam performance.

## alternative hypothesis?

- $H_1 : \rho \neq 0$
- There **is a relationship** between exam anxiety and exam performance.

When  $r$  is farther from 0,  $p$  will be smaller.

- **Our  $r$  and associated  $p$ -value tell us about the credibility of the null hypothesis.**
- Let's set our  $\alpha = .01$ .

# Correlation:

## How to run in JAMOVI

**Click over two relevant variables** (or more than two, if you're asked to examine the relationships between more than one pair of variables).

*In this first example, let's examine whether exam anxiety is related to exam performance.*

**Click the box for N** in order to get the sample size.

Leave everything else the same. (Your screen should look like the one on the right.)

The screenshot shows the JAMOVI software interface with the 'Analyses' tab selected. The 'Correlation Matrix' dialog box is open, showing the following settings:

- Variables:** 'Exam' and 'Anxiety' are selected in the right-hand box.
- Correlation Coefficients:** 'Pearson' is checked.
- Additional Options:** 'Report significance' is checked, and 'N' is checked and circled in red.
- Hypothesis:** 'Correlated' is selected.
- Plot:** 'Correlation matrix' is selected.

The top of the interface shows the 'jamovi - Exam\_Anxiety' title bar and the 'Data' and 'Analyses' tabs. The bottom of the interface shows the 'Correlation Matrix' dialog box with a search bar and a list of variables: 'Code', 'Revise', and 'Gender'.

# Outline for Ch. 12 Correlation – using JAMOV

---

1. How to run correlation using JAMOV
- 2. How to interpret JAMOV output**
3. How to write up results using APA style

To help us **interpret**  $r$ , we can start by looking at our  $p$ -value & comparing it to the alpha we set.

Remember the guidelines:

$p < \alpha \rightarrow$  reject null; there's a significant relationship

$p > \alpha \rightarrow$  retain null; there is no significant relationships

# Correlation Matrix

## Correlation Matrix

Exam      Anxiety

|         |               |        |
|---------|---------------|--------|
| Exam    | Pearson's $r$ | —      |
|         | p-value       | —      |
|         | N             | —      |
| Anxiety | Pearson's $r$ | -0.44  |
|         | p-value       | < .001 |
|         | N             | 103    |

The correlation coefficient,  
 $r = -.44$   
(\*\*Remember to pay attention to  
the positive or negative sign.)

The p-value  
associated with our  
 $r$  of -.44. Indicates  
whether to reject  
or retain the null  
hypothesis.

Sample size,  $N = 103$

The two variables we  
are examining the  
relationship between.

# Interpreting output from a correlational analysis

Slide 9

## Interpret $r$ . (from handout)

We *reject* the null hypothesis b/c  $p < .001$ , which is also less than our  $\alpha$  of .01.

There is a significant negative relationship between exam performance and exam anxiety.

- As exam anxiety goes up, exam performance worsens.
- The effect size is medium-to-large (or There is a moderate-to-strong relationship).
- 19% of the variability in exam performance can be explained by a person's exam anxiety.

## Correlation Matrix

$$R^2 = (-.44)(-.44) = .19 \text{ or } 19\%$$

Correlation Matrix

|         |             | Exam   | Anxiety |
|---------|-------------|--------|---------|
| Exam    | Pearson's r | —      |         |
|         | p-value     | —      |         |
|         | N           | —      |         |
| Anxiety | Pearson's r | -0.44  | —       |
|         | p-value     | < .001 | —       |
|         | N           | 103    | —       |

Assume  $\alpha = .01$ .

You can run correlations for multiple pairs of variables at a time.

Use the same procedure as before, just click over whichever variables you are interested in.

JAMOVI will run a correlational analysis for each pair, separately.

The screenshot displays the JAMOVI software interface for the 'Exam\_Anxiety' dataset. The 'Analyses' tab is active, showing icons for Exploration, T-Tests, ANOVA, Regression, Frequencies, and Factor. The 'Correlation Matrix' analysis is selected, and its configuration window is open. In the 'Variables' list on the left, 'Code' and 'Gender' are visible, with 'Gender' selected. On the right, a red box highlights the variables 'Anxiety', 'Exam', and 'Revise' that have been added to the analysis. Below the variable lists, the 'Correlation Coefficients' section has 'Pearson' selected. The 'Additional Options' section has 'Report significance', 'N', and 'Confidence intervals' (set to 95%) selected. The 'Hypothesis' section has 'Correlated' selected. The 'Plot' section has 'Correlation matrix', 'Densities for variables', and 'Statistics' selected.

## Correlation in JAMOVl:

Output for correlation between exam performance, exam anxiety, and time spent revising

1. What is the correlation between exam anxiety and time spent "revising" aka studying?
2. What's the p-value for that correlation? Assume  $\alpha=.01$ . Is the correlation statistically significant? How do you know?
3. Is the relationship weak, moderate, or strong? Should you interpret the effect size at all?
4. What % of the variance in time spent studying is shared by exam anxiety?
5. Which pair of variables has the weakest relationship?
6. For the pair of variables you identified in question 5, finish this statement indicating the direction of their relationship: *As time spent studying increases, ...*

### Correlation Matrix

Correlation Matrix

|         |             | Anxiety | Exam   | Revise |
|---------|-------------|---------|--------|--------|
| Anxiety | Pearson's r | —       |        |        |
|         | p-value     | —       |        |        |
|         | N           | —       |        |        |
| Exam    | Pearson's r | -0.44   | —      |        |
|         | p-value     | < .001  | —      |        |
|         | N           | 103     | —      |        |
| Revise  | Pearson's r | -0.71   | 0.40   | —      |
|         | p-value     | < .001  | < .001 | —      |
|         | N           | 103     | 103    | —      |

## Correlation in JAMOVl:

Output for correlation between exam performance, exam anxiety, and time spent reviewing

1. What is the correlation between exam anxiety and time spent revising?

**$r = -.71$**  (don't forget the negative sign!)

2. What is the p-value? Assuming  $\alpha = .01$ , is that correlation statistically significant? How do you know?

**$p < .001$ . Yes, it is significant because it is less than .01**

3. Is that relationship weak, moderate, or strong? Should you interpret the effect size at all?

**Large, because the absolute value of  $r$  is at least .50.**

We *should* interpret the effect size since the relationship is statistically significant (i.e, since  $p < \alpha$ ).

## Correlation Matrix

Correlation Matrix

|         |             | Anxiety | Exam   | Revise |
|---------|-------------|---------|--------|--------|
| Anxiety | Pearson's r | —       |        |        |
|         | p-value     | —       |        |        |
|         | N           | —       |        |        |
| Exam    | Pearson's r | −0.44   | —      |        |
|         | p-value     | < .001  | —      |        |
|         | N           | 103     | —      |        |
| Revise  | Pearson's r | −0.71   | 0.40   | —      |
|         | p-value     | < .001  | < .001 | —      |
|         | N           | 103     | 103    | —      |

## Correlation in JAMOVl:

Output for correlation between exam performance, exam anxiety, and time spent reviewing

4. What % of the variance in time spent studying is shared by exam anxiety?

Calculate the *coefficient of determination*,

$$R^2 = -.71 * -.71 = .5041 \sim \mathbf{50\%}$$

5. Which pair of variables has the *weakest* relationship?

**Exam performance and time spent revising (studying).**

The  $r = .40$ , which has the smallest absolute value compared with  $-.44$ , and  $-.71$ . It is the closest to zero; however it is still statistically significant.

6. *As time spent studying (revising) increases,*  
**exam performance increases.**

You could also describe this relationship as: *As time spent studying decreases, exam performance decreases.* **OR**

*As exam performance increases, time spent studying increases.*

Correlation Matrix

|         |             | Anxiety | Exam   | Revise |
|---------|-------------|---------|--------|--------|
| Anxiety | Pearson's r | —       |        |        |
|         | p-value     | —       |        |        |
|         | N           | —       |        |        |
| Exam    | Pearson's r | -.44    | —      |        |
|         | p-value     | < .001  | —      |        |
|         | N           | 103     | —      |        |
| Revise  | Pearson's r | -.71    | .40    | —      |
|         | p-value     | < .001  | < .001 | —      |
|         | N           | 103     | 103    | —      |

Flip the page over on your handout for a new example . . .

---

- A record label collected data for each band on four variables:
  - Sales – album sales for the band
  - Airplay – # of plays on the radio for the band's songs
  - Adverts – advertising budget for the band's albums
  - Attract – how attractive the band members are

1. What is the sample size?

**$N = 200$  bands**

2. What null & alternative hypotheses (in symbols) are being tested for each pair of variables?

**$H_0 : \rho = 0$**

**$H_1 : \rho \neq 0$**

|               | N           | 15            | —        |

# Is the amount of alcohol you consume in a night related to how happy you are?

Slide 22

3. What is the correlation between the number of drinks a person normally has when he/she drinks and how happy that person was on the day he/she completed the survey?  **$r = -.58$**
4. What is the p-value associated with this correlation? Is this correlation statistically significant, assuming  $\alpha = .05$ ? Do you reject or retain the null hypothesis?  **$p = .024$ , so yes, the correlation is statistically significant and we will reject the null hypothesis that there's no relationship.**
5. How would you describe this relationship in words? That is, interpret  $r$  (referring to significance (or not), and, if significant, referring to direction, strength (effect size), and coefficient of determination). Write in full sentences

**The amount of alcohol someone drinks is significantly negatively related to how happy they are; the more someone drinks, the less happy they report being. This effect represents a large effect size.**

$$R^2 = -.58 * -.58 = .3364 \sim 34\%$$

**Thirty-four percent of the variability in people's happiness is explained by how much they drink. OR, Thirty-four percent of the variability in people's drinking habits is explained by how happy they are.**

# Outline for Ch. 12 - Correlation

# Watch Commercials, Buy Candy?

Imagine that 5 people were asked how many advertisements (commercials) for a certain candy they saw one week, and then researchers measured how many packets of that candy they purchased the next week . . .

Relevant research question: Is the # of candy commercials you saw one week related to the # of candy packets you purchased the next week?

**TABLE 6.1**

| Subject         | 1 | 2 | 3  | 4  | 5  | Mean | S    |
|-----------------|---|---|----|----|----|------|------|
| Adverts Watched | 5 | 4 | 4  | 6  | 8  | 5.4  | 1.67 |
| Packets Bought  | 8 | 9 | 10 | 13 | 15 | 11.0 | 2.92 |

# Reporting correlations in APA-style p

Say that you ran a correlational analysis and list the two variables that went into it.

## Results

To examine whether there was a relationship between number of commercials watched and the amount of candy purchased, we ran a correlational analysis using these two variables. There is a significant positive correlation between number of commercials watched and amount of candy purchased,  $r(5) = .87, p = .034$ . As the number of commercials watched increases, the amount of candy purchased increases. This relationship has a large effect size. Also, 76% of the variance in how much candy people purchased is explained by the number of commercials people watched.

Your Pearson's  $r$

Specify not only that you have a significant correlation, but that the direction is *positive*.

Italicize  $r$

Sample size in parentheses

Italicize  $p$ , but not the value of  $p$ .

Since our  $p$ -value is less than  $\alpha$  (which is .05), this correlation is *statistically significant*.

## Results

To examine whether there was a relationship between number of commercials watched and the amount of candy purchased, we ran a correlational analysis using these two variables. There is a significant positive correlation between number of commercials watched and amount of candy purchased,  $r(5) = .87$ ,  $p = .034$ . As the number of commercials watched increases, the amount of candy purchased increases. This relationship has a large effect size. Also, 76% of the variance in how much candy people purchased is explained by the number of commercials people watched.

Effect size is large b/c any  $r$  that is .50 or greater is considered large, and here,  $r$  is .87.

Alternatively, you can state:

These variables have a strong relationship.

This is the  $R^2$ . Turn the  $R^2$  decimal into a % by multiplying by 100.

The format of this final statement will always be the same. You state that the "% of the variance in [insert one of your two variables] is shared by (or 'is explained by') [insert other variable]."

Use the variable names here, rather than saying more/less of that variable. e.g., say "how much candy" vs. "more candy" or "less candy"

- Example from earlier in this lecture, on exam anxiety, performance and studying.

## Correlation Matrix

Correlation Matrix

|         |             | Anxiety | Exam   | Revise |
|---------|-------------|---------|--------|--------|
| Anxiety | Pearson's r | —       |        |        |
|         | p-value     | —       |        |        |
|         | N           | —       |        |        |
| Exam    | Pearson's r | −0.44   | —      |        |
|         | p-value     | < .001  | —      |        |
|         | N           | 103     | —      |        |
| Revise  | Pearson's r | −0.71   | 0.40   | —      |
|         | p-value     | < .001  | < .001 | —      |
|         | N           | 103     | 103    | —      |

## Results

To examine whether exam anxiety, exam performance, and time studying were related, we ran correlational analyses using these three variables. We observed a significant negative correlation between exam anxiety and exam performance ( $r(103) = -.44, p < .001$ ), such that higher anxiety was associated with worse exam performance. This is a moderate-to-strong relationship, and approximately 19% of the variation in exam performance can be explained by exam anxiety. We also observed a significant positive relationship between time spent studying and exam performance ( $r(103) = .40, p < .001$ ), such that more time spent studying was associated with better exam performance, a relationship that was moderate to strong (or just moderate) in size. About 16% of the variation in exam performance can be explained by how much time students spent studying. Finally, we observed a significant negative correlation between exam anxiety and time spent studying ( $r(103) = -.71, p < .001$ ), a strong relationship. Greater exam anxiety was associated with less time spent studying. About half the variation in time spent studying is shared by exam anxiety.

## APA-STYLE RESULTS SECTION FROM PAGE 6 OF HANDOUT

### Results

We ran two correlational analyses to examine, first, whether the number of alcoholic drinks a person themselves drinks is related to the number of drinks they believe their typical peer drinks per night of drinking, and second, whether the number of alcoholic drinks a person themselves drinks is related to that person's self-reported happiness at the time of the survey. There was no significant relationship between the number of alcoholic drinks people normally drink and the number of drinks they believe others normally drink,  $r(15) = .09, p = .75$ . In other words, whether a person normally drinks a lot or a little is not related to their perceptions of **how much others normally drink**. There was, however, a significant negative relationship between **how much a person normally drinks** and how happy they were on the day of the survey,  $r(15) = -.58, p = .024$ . In particular, the more a person normally drinks, the **less happy they were on the day they took the survey**. The number of drinks a person normally drinks shared **34%** of its variance with how happy a person was on the day of the survey, and the relationship between the two variables was **strong**.
